ard Sherley Linear models in R

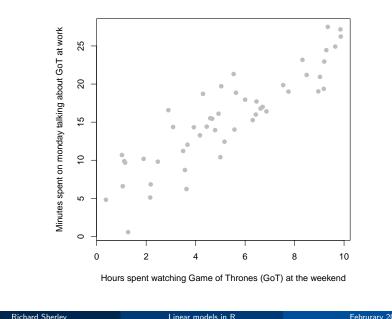

# What is a model and why do we need one?

A **model** is a human construct/abstraction that tries to approximate the **data generating process** in some useful manner

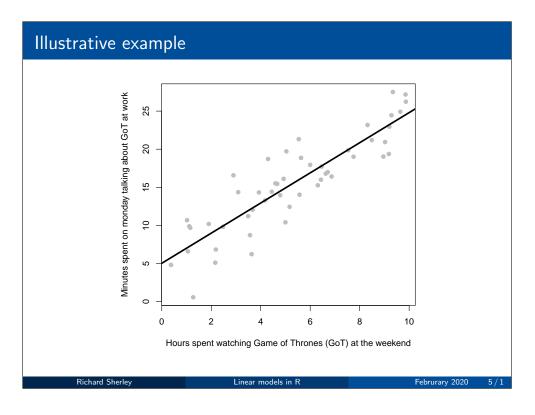

### Models are built for

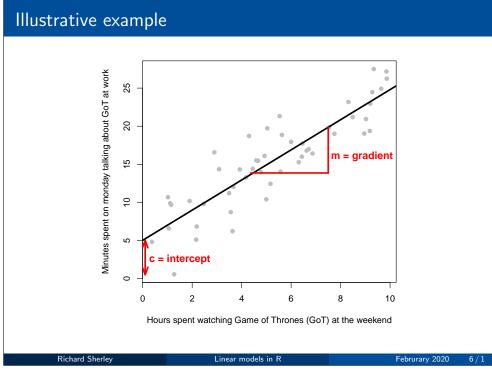

- enhancing our understanding of a complex phenomenon
- executing "what if" scenarios
- predicting/forecasting an outcome
- controlling a system

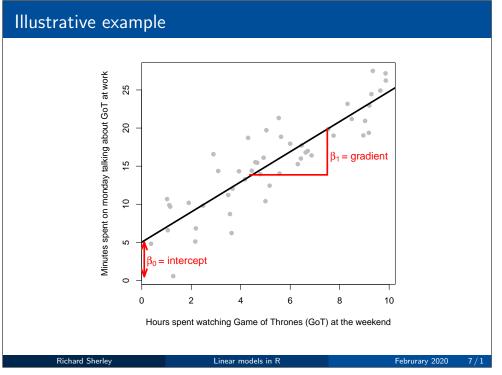

# Illustrative example

Richard Sherley Linear models in R February 2020 3/1

# Formal definition

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$
$$\epsilon_i \sim \mathcal{N}(0, \sigma^2)$$

### Observed data

- ullet y (outcome/response): minutes spent talking about GoT
- x (explanatory): hours spent watching Game of Thrones (GoT)

### Parameters to infer

- $\beta_0$ : intercept
- $\beta_1$ : gradient wrt minutes talking about GoT

Richard Sherley Linear models in R Februrary 2020 8 /

### Linear models in R

- Use the lm() function
- Requires a **formula** object outcome  $\sim$  explanatory variable

```
1 # talk: minutes spent talking about GoT (outcome/response variable)
2 # watch: hours spent watching GoT (explanatory variable)
4 fit <- lm(talk ~ watch)
6 # If data is in a data frame called "df"
7 fit <- lm(talk ~ watch, df)</pre>
```

# Summary of fitted model

```
summary(fit)
## Call:
## lm(formula = height ~ weight, data = df)
## Residuals:
      Min
               1Q Median
## -31.089 -6.926 -0.689 6.057 24.967
## Coefficients:
             Estimate Std. Error t value Pr(>|t|)
## (Intercept) 2.35229 7.11668 0.331
## weight
               ## Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' 1
## Residual standard error: 10.31 on 98 degrees of freedom
## Multiple R-squared: 0.8622, Adjusted R-squared: 0.8608
## F-statistic: 613.1 on 1 and 98 DF, p-value: < 2.2e-16

                                                            Februrary 2020 10 / 1
```

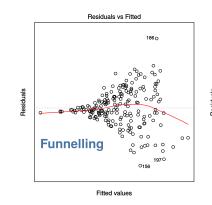

# Model checking

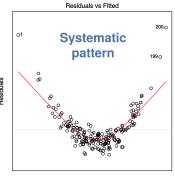

In order to make robust inference, we must check the model fit

```
plot(fit)
                                                                          Februrary 2020
```

# Model checking

A couple of examples where the homogeneity of variance assumption is violated

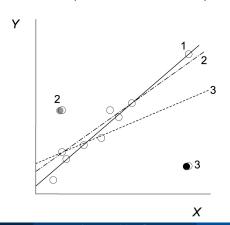

Februrary 2020

# Model checking: Leverage and Influence

- Obs. 1 large leverage (outlier in x and y), but not influential
- Obs. 2 large residual, but not an outlier in x or y. Not influential
- Obs. 3 not an outlier for y, but has large **leverage and large residual**: very influential (high Cook's distance).

# Model checking: Plot your data!

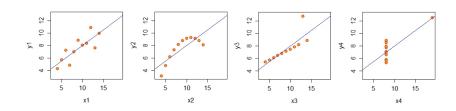

- Always visualise your data before fitting any model
- Assumption of a linear relationship...
- Scatterplots can indicate unequal variance, nonlinearity and outliers

Februrary 2020

# Model checking: Plot your data!

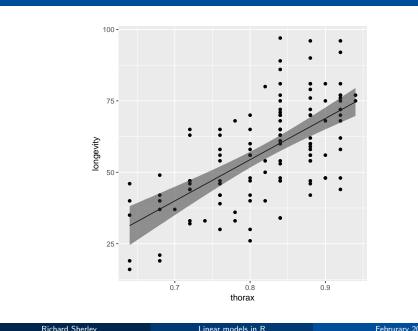

- Always visualise your data before fitting any model
- Assumption of a linear relationship...
- Scatterplots can indicate unequal variance, nonlinearity and outliers

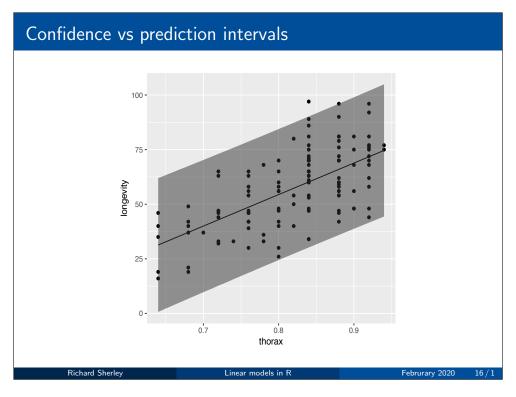

# Anscombe (1973) American Statistician 27: 17-21

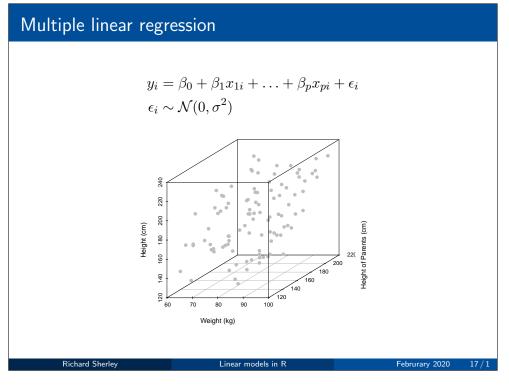

- $r^2 = 0.68$  in all four cases
- Test that  $H_0=0$  identical in all four cases ( $t=4.24,\,P=0.002$ )

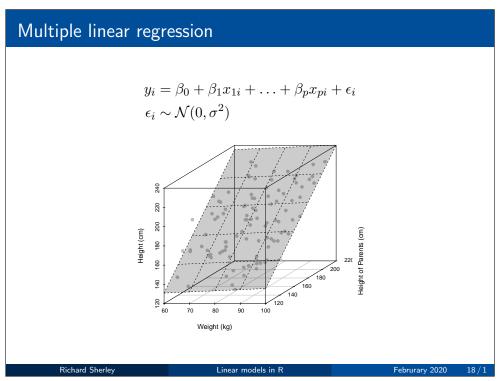

# Confidence vs prediction intervals

# Categorical variables

We need **dummy** variables

$$S_i = \begin{cases} 1 & \text{if } i \text{ is male,} \\ 0 & \text{otherwise} \end{cases}$$

Here, female is known as the **baseline/reference level** The regression is:

$$y_i = \beta_0 + \beta_1 S_i + \beta_2 x_i + \epsilon_i$$

Or in English:

Richard Sherley

$$height_i = \beta_0 + \beta_1 sex_i + \beta_2 weight_i + \epsilon_i$$

Linear models in R

Categorical variables

The mean regression lines for male and female are:

• Female (sex=0)

$$\begin{aligned} \text{height}_i &= \beta_0 + (\beta_1 \times 0) + \beta_2 \text{weight}_i \\ \text{height}_i &= \beta_0 + \beta_2 \text{weight}_i \end{aligned}$$

• Male (sex=1)

Februrary 2020 20 / 1

$$\begin{aligned} \text{height}_i &= \beta_0 + (\beta_1 \times 1) + \beta_2 \text{weight}_i \\ \text{height}_i &= (\beta_0 + \beta_1) + \beta_2 \text{weight}_i \end{aligned}$$
